

**Figure 6.5a.** A 55-year-old woman with a 10-year history of a progressively enlarging mass of the left cheek that is able to be visualized inferior to her left zygomatic buttress when she opens her mouth. She reported a history of Sjogren's syndrome.

**Figure 6.5b.** Computerized tomograms identified a heterogenous mass of the left buccal region, associated with minor salivary gland tissue vs. an accessory parotid gland. A salivary gland neoplasm was favored based on clinical and radiographic information.

**Figure 6.5c.** Excision was accomplished with a Weber-Ferguson incision so as to provide access and minimize trauma to Stenson's duct and the buccal branch of the facial nerve.
